

VSS has been performing arthroscopy for many years with excellent outcomes.

Arthroscopy is where we look inside the joint with a small camera. It is a minimally invasive procedure and therefore pets can recover from the surgery very quickly.

Common arthroscopic procedures are;

- in conjunction with **cruciate ligament stabilisation surgery**, to examine the joint and treat any damage to the meniscus cartilage (C-shaped cartilages inside the knee joint).
- to diagnose and help **treat osteochondritis dissecans (OCD)**. Arthroscopy can be used to remove loose cartilage or bone fragments from the joint and debride underlying bone,

which can help relieve pain and improve joint function.

- to remove elbow coronoid fragments associated with **elbow dysplasia**.

Common joints arthroscopically explored are the stifle (knee), shoulder and elbow.

Because arthroscopy is less invasive than traditional open surgery, it can mean less pain, less scarring, and a faster recovery time for dogs.
